Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid. (Art. 99(1) European Patent Convention).

Description

[0001] This invention relates to an expandable sheath assembly and more particularly to a large-diameter expandable sheath assembly for use in introducing a catheter into a vessel in the body of a patient.

[0002] Expandable access catheter assemblies have heretofore been provided to facilitate the placement and removal of diagnostic and therapeutic catheters through the vascular system. Such catheter assemblies included a flexible variable-diameter catheter body, a diameter control stylet and a flexible Y-hub. The flexible Y-hub incorporates an adjustable hemostasis valve and a side port in one branch and a diameter control stylet guide wire in another branch. A flexible variable diameter catheter body is secured to the flexible Y-hub and can be expanded between a collapsed position and an expanded position by the stylet guide wire. Several deficiencies have been found in such a device. For example, the adjustable hemostasis valve is incapable of accepting large catheters. The flexible variable-diameter catheter body is objectionable in that it has a tendency to reduce in diameter and hold onto large-diameter catheters when it is attempted to place the same through the catheter body. In addition, the tip of the stylet guide wire catches a large-diameter catheter which causes elongation of the catheter body and reduction in its diameter to grab and prevent further advancement of the large-diameter catheter.

[0003] In the prior art US-A-4,580,573 describes a catheter introducer having an axially disposed cylindrical elastic segment which covers first and second substantially solid cylindrical elements. Also described are means for rotatably securing said first and second elements relative to a common longitudinal axis for facilitating a reduction in diameter of said elastic segment in order to perform a fluid-tight seal against any elongated element placed along and within said longitudinal axis. A catheter so introduced may be advanced, withdrawn, held, or otherwise manipulated without loss of the fluid or atmospheric seal between the internal diameter of the elastic segment and the object introduced.

[0004] By contrast, US-A-4,540,411 describes a catheter placement device which includes a catheter, a pair of relatively rotatable valve members connected to the catheter, an elastomeric longitudinally extending tubular member connected between the valve members and twistable in response to relative rotation of the valve members, and an introducer needle extending longitudinally through the tubular member and catheter for introducing the distal end of the catheter into a blood vessel. Predetermined relative rotation between the valve members effects twisting of the tubular member about the needle and closure of the tubular member.

[0005] Nevertheless there remains a need for a new and improved large-diameter expandable sheath assembly which will overcome the above described deficiencies.

[0006] In general, it is an object of the present invention to provide an expandable sheath assembly which can be utilized with large-diameter catheters.

[0007] Another object of the invention is to provide a sheath assembly of the above character which is provided with a backflow adapter which includes a tubular diaphragm that can be moved into a hourglass or iris-like configuration to create a fluid-tight barrier around any tubular device such as a large-diameter catheter passed through the backflow adapter and the tubular diaphragm.

[0008] Another object of the invention is to provide a sheath assembly of the above character in which the backflow adapter can be readily controlled.

[0009] Another object of the invention is to provide a sheath assembly of the above character which is folded longitudinally to a small diameter and which can be expanded greatly when a large-diameter catheter is to be passed through it.

[0010] Another object of the invention is to provide a sheath assembly of the above character in which a dilator can be utilized for expanding the sheath.

[0011] According to a first aspect of the present invention there is provided a large-diameter expandable sheath assembly for use in introducing a catheter into a vessel in a body of a patient comprising an elongate sheath tube formed of a flexible material having proximal and distal extremities and having a passage extending therethrough of a maximum predetermined diameter; and a backflow adaptor secured to the proximal extremity of the elongate sheath tube, said backflow adaptor having a central opening therein in registration with the passage in the sheath tube and valve means disposed in the said central opening of the backflow adaptor and movable between an open position in which the catheter is permitted to be inserted into the sheath and a closed position in which the valve means serves to form a hemostatic seal about the catheter, the valve means being in the form of a cylindrical member formed of a flexible material and having a bore therein in registration with the central opening, together with means carried by the backflow adapter for engaging opposite ends of said cylindrical member to enable one of said ends to be rotated relative to the other thereby twisting the cylindrical member and closing the bore, said means for enabling relative rotation between opposite ends of said cylindrical member including a retaining ring and sheath tube adapter secured to opposite ends of said cylindrical member, means for fixing the sheath tube adapter to prevent rotation of the same within the backflow adapter and means carried by the backflow adapter for rotating the retaining ring with respect to the sheath tube adapter, characterised in that said means for enabling relative rotation between opposite ends of said cylindrical member further includes a ring gear secured to said retaining ring and rack means for driving said ring gear to cause rotation of the same.

[0012] Additional objects and features of the invention

will appear from the following description in which the preferred embodiments are set forth in detail in conjunction with the accompanying drawings.

Figure 1 is a side elevational view of a large-diameter expandable sheath assembly incorporating the present invention and in which a sheath introducer is disposed in the sheath.

Figure 2 is an enlarged side elevational view of the sheath introducer shown in the large-diameter expandable sheath assembly of Figure 1.

Figure 3 is an enlarged detail view partially in cross-section of the distal extremity of the sheath introducer shown in Figure 2.

Figure 4 is a cross-sectional view taken along the line 4-4 of Figure 1.

Figure 5 is a partial side elevational view of an alternative embodiment of an expandable sheath.

Figure 6 is a cross-sectional view taken along the line 6-6 of Figure 5.

Figure 7 is a cross-sectional view similar to Figure 4 showing the sheath of Figures 5 and 6.

Figure 8 is an enlarged side elevational view partially in cross-section of the proximal extremity of the large expandable sheath of the sheath assembly shown in Figure 1 and particularly showing the backflow adapter.

Figure 9 is an end elevational view looking along the line 9-9 of Figure 8 with certain portions being shown in cross-section and with the valve carried by the backflow adapter being in a normally closed position.

Figure 10 is a view similar to Figure 9, but showing the valve in an open position.

Figure 11 is a side elevational view partially in cross section opposite the side shown in Figure 8 of the proximal extremity of the expandable sheath.

Figure 12 is a bottom plan view looking along the line 12-12 of Figure 11.

Figure 13 is a top plan view looking along the line 13-13 of Figure 11.

Figure 14 is a side elevational view of the valve or diaphragm utilized in the backflow adapter shown in Figures 9 and 10.

Figure 15 is an alternative embodiment of a valve or diaphragm for use in the backflow adapter shown in Figures 9 and 10.

Figure 16 is still another embodiment of a valve or diaphragm for use in the backflow adapter shown in Figures 9 and 10.

Figure 17 is a view similar to Figure 9 but showing an alternative rack and pinion arrangement for the backflow adapter.

Figure 18 is a cross-sectional view showing another embodiment of a rack for the closing and opening of the valve in the backflow adapter.

Figure 19 is a cross-sectional view taken along the line 12-12 of Figure 18.

[0013] In general, the large-diameter expandable sheath is used for introduction of a catheter into the body of a patient. It comprises an elongate sheath tube formed of a flexible material and having proximal and distal extremities and having passage therein of a predetermined maximum diameter. The distal extremity of the elongate sheath tube is folded longitudinally into a smaller diameter. A backflow adapter is secured to the proximal extremity of the elongate sheath tube. The backflow adapter has a central opening therein in registration with the passage in the sheath tube. Valve means is disposed in the central opening in the backflow adapter and is movable between open and closed positions. The valve means when in an open position permits a catheter to be introduced into the sheath and when closed forms a liquid-tight seal about the catheter extending therethrough.

[0014] More particularly as shown in Figure 1 of the drawings, the large-diameter expandable sheath 11 consists of an elongate sheath tube 12 having proximal and distal extremities 13 and 14 and having a flow passage 16 having a maximum diameter extending therethrough. The expandable sheath 11 can have a suitable length as, for example, 15-35 centimeters and preferably approximately 18 centimeters with a maximum outside diameter of 1 centimeter. The elongate sheath tube is formed of a flexible material having a wall thickness of 2.54×10^{-3} cm to 0.0508 cm (.001 to .020 inches) and preferably about 0.0127 cm (.005 inches) and can be formed of a suitable plastic material such as Teflon™ (a fluorinated ethylene polypropylene). An alternate material is Tefzel™ (ethylene tetrafluoroethylene). The selected material should have physical characteristics which will not be compromised by radiation sterilization.

[0015] The distal extremity of the sheath tube is pleated or folded longitudinally as shown in Figure 4 to provide wraps or folds 17 for a distance of approximately 10 centimeters from the distal end to provide a distal extremity of reduced diameter as, for example, a

reduction of the outside diameter from 0.9525 cm to 0.47625 cm (3/8" to 3/16") or approximately one-half the original size. The folding or pleating of the sheath tube 12 in this manner serves two purposes. The first purpose is to reduce the sheath diameter to facilitate introduction of the sheath and to make it less traumatic for the vessel into which it is introduced. The second reason is that with a small-diameter, thin-wall tube, as represented by the elongate sheath tube 12, there is less likelihood of kinking occurring than in a large-diameter, thin-wall tube. The distal extremity of the sheath tube 12, when folded longitudinally in this manner, serves to provide kink resistance in the distal extremity 14 while still being relatively flexible.

[0016] If it is desired to further decrease the likelihood of kinking in the large-diameter, thin-wall tube which forms the sheath tube 12, another embodiment of the sheath tube can be provided of the type shown in Figures 5, 6 and 7. The sheath tube 18 shown in those figures is provided with a plurality of circumferentially spaced apart flexible elongate elements 19 which are embedded in the wall of the tube 18 and extend longitudinally along the length thereof as shown in Figure 5. The proximal extremities are offset or staggered as shown in Figure 5 with alternate elements 19 being shorter. This offset relationship provides a gradation in stiffness in the proximal extremity of the sheath tube 18. The elongate elements 19 can be in the form of stainless steel wires having a diameter ranging from 0.0127 cm to 0.0381 cm (.005" to .015") and preferably a diameter of approximately 0.0254 cm (.010"). As can be seen from Figure 6, the sheath tube 18 can bulge outwardly around the elongate elements 19 while being relatively thin between the elongate elements to retain the flexibility of the tube 18. As also can be seen from Figure 6, the elongate elements 19 are spaced apart in the three groups to facilitate the formation of six folds 20 as shown in Figure 7. Thus, by way of example, each set of elongate elements can have the elongate elements spaced approximately 35° apart with each set being spaced approximately 85° apart. Spacing of the elongate elements 19 in this manner facilitates the formation of the folds shown in Figure 7. The elongate elements 19 also provide additional rigidity longitudinally of the tube 18 so as to inhibit accordioning of the tube 18 during removal of the introducer as hereinafter described.

[0017] A backflow adapter 21 is secured to the proximal extremity of the elongate sheath tube 12. The backflow adapter 21 consists of a housing or body 22 which is formed of a suitable material, such as plastic. The housing 22 is provided with a central bore 23 extending therethrough in axial alignment with the passage 16 of the sheath tube 12. A cylindrical sheath tube adapter 26 is disposed in the bore 23 and is provided with an annular recess 27 which receives an inwardly-extending flange 28 provided on the proximal extremity 13 of the sheath tube 12 (see Figure 8). A tubular insert 29 formed of the same material as the sheath tube 12 but

of a greater wall thickness, as for example twice the wall thickness of the sheath tube 12, is secured within an annular recess 30 in the sheath tube adapter 26 by suitable means such as an adhesive. The insert 29 serves as a reinforcement and serves to prevent collapse of the proximal extremities 13 of the sheath tube 12 when the expandable sheath 11 is used. The sheath tube adapter 26 is fixed within a first cylindrical collar 31 seated within the bore 23 and is held in place by solvent bonding the cylindrical collar 31 into the housing or body 22 to prevent longitudinal and/or rotational movement of the first collar 31 relative to the housing or body 22. A second collar 34 is also seated in the bore 23 and is rotatable therein. An annular ring gear 36 having teeth 37 thereon is also rotatably mounted in the bore 23 as hereinafter described.

[0018] A cylindrical or tubular valve member or diaphragm 40 is disposed between the first and second collars 31 and 34, and is provided with a bore or flow passage 41 extending therethrough. The valve member 40 is provided with inwardly extending annular lips or flanges 42 and 43 provided on opposite extremities of the same (see Figures 8 and 14). The flange 43 is seated in an annular recess 46 in the sheath tube adapter 26 and is retained therein by the first collar 31. The flange 42 is seated in an annular recess 47 provided in a retaining ring 48 and retained therein by the second collar 34. An annular protrusion 49 is formed integral with the retaining ring 48 and engages one side of the toothed ring gear 36 which is secured to the retaining ring 48 by suitable means such as an adhesive. Similarly, the retaining ring 48 functionally engages the second collar 34 and causes the second collar 34 to rotate therewith.

[0019] The diaphragm or valve member 40 can have a suitable size as, for example, a length of 0.762 - 1.143 cm (0.30 - 0.45") and preferably a length of approximately 0.762 cm (0.30"), and an inside diameter of 0.889 - 1.27 cm (0.35 - 0.500"), and preferably an inside diameter of 0.9525 cm (0.375"), with a wall thickness ranging from 0.0127 cm to 0.0381 cm (0.005" to 0.015"), and preferably a wall thickness of 0.01778 cm (0.007"). The annular lips 42 and 43 can extend inwardly for a distance of 0.08128 cm (0.032") from the outer wall surface and have a length of approximately 0.127 cm (0.050"). The diaphragm or valve member 40 can be formed of a suitable material, such as a silicone elastomer, as, for example, Dow Silastic 97-4720. It can have a Shore A hardness ranging from 20-80 and preferably a Shore hardness of 40A. Alternatively, a low durometer, tear-resistant rubber-like latex material can be utilized.

[0020] Other diaphragm or valve members such as shown in Figures 15 and 16 can be utilized which have the same physical conformation. In the embodiment shown in Figure 15, small diener polyester fibers 52 are bonded to the exterior surface of the diaphragm 51 with a silicone adhesive so that the fibers 52 extend circum-

ferentially around the outside surface of the diaphragm 51. Such fibers serve to impede radial and longitudinal distention of the diaphragm or valve member 51. The diaphragm or valve member 56 shown in Figure 16 is provided with a cylindrical wall 57 which increases in thickness in a direction towards the distal extremity of the diaphragm. This helps the diaphragm to withstand the pressures applied to the diaphragm during use, which may cause the diaphragm to distend and leak.

[0021] Means is provided for causing relative rotation between the sheath tube adapter 26 and the retaining ring 48 for opening and closing the bore or flow passage 41 by twisting of the cylindrical valve member or diaphragm 40. This is accomplished by fixing the first collar 31 and the sheath tube adapter 26 within the housing or body 22 by suitable means such as solvent bonding and causing rotation of the retaining ring 48 by the use of a rack 61. The rack 61 consists of a rod 62 formed of a suitable material such as stainless steel which extends through a hole 63 (see Figure 11) in the housing or body 22 in a direction which is tangential of the bore 23. The rod 62 is disposed immediately adjacent a flange formed in the body 22 against which the ring gear 36 rotates. The hole 63 opens into the bore 23 so that rack teeth 64 provided on the one side of the rod 62 engage the toothed ring gear 36 whereby upon reciprocatory movement of the rack 61, the ring gear 36 is rotated through an angle ranging from 180° to 360°, and preferably an angle of at least 270°.

[0022] An actuator 66 formed of a suitable material such as plastic is mounted on the upper extremity of the rod 62 and is secured thereto by suitable means such as an Allen-head screw 67 set into the rod 62 as shown in Figure 13. The actuator 66 is generally rectangular in plan and is provided with an upstanding lip 68 so that it conforms to the conformation of the index finger of the hand which is to be utilized for actuating the rack 61. The actuator 66 is provided with a reinforcing rib 69 along one edge of the same. A similar actuator member 71 is provided on the body 22 underlying the actuator 66 and is also provided with a downwardly extending lip 72. The actuator member 71 is secured to the body 22 by suitable means such as an adhesive. The member 71 also has a rectangular configuration in plan and is sized so that it is adapted to be engaged by the thumb of the hand as shown in Figure 12. Thus, one hand can be utilized for operating the backflow adapter 21 by the index finger of the hand grasping the actuator 66 and the thumb of the same hand grasping the member 71.

[0023] A stabilization and guide rod 76 extends through a tangential bore 77 (see Figure 11) provided in the body 22 which is spaced apart from the bore 63 and extends in a direction which is parallel thereto. The rod 76 is formed of a material such as stainless steel and is provided with a collar 78 which extends through the reinforcing rib 69 of the actuator 66 and is secured therein by suitable means such as an Allen-head screw 79.

[0024] Means is provided for yieldably returning the rack 61 into a position so that the valve member or diaphragm 40 is in a normally closed position and consists of a coil spring 81 coaxially mounted on the rod 62 and having one end engaging the actuator 66 and having the other end engaging a seat 82 provided in the body 22. Means is provided for preventing the spring 81 from urging the rod 62 out of the bore 63 and consists of a lump 83 of solder or a braising material provided on the rod 62 adjacent the lower extremity of the rack teeth 64. Thus, it can be seen by the hand engaging the backflow adapter 21 using the index finger to engage the actuator 66 and the thumb to engage the actuator member 71, the rack 61 can be reciprocated back and forth to open and close a bore 86 extending through the retaining ring 48 and the sheath tube adapter 26 by forming an hour-glass or iris-like closure as shown in Figure 9 in which the radially extending lines 87 shown represents the folding over of the elastomeric material of the valve member or diaphragm 40. The collar 78 provided on the stabilization rod 76 serves to stop further travel up the rack when the collar 78 engage a seat 88 provided in the body 22. In this position, the spring 81 is almost completely compressed as shown in Figure 10. Following the release of the actuator 66, the spring 81 returns the rack 62 to its home position and causes the valve member or diaphragm 40 to be completely closed as shown in Figure 9.

[0025] The ring gear 36 can be formed of a suitable material such as stainless steel and can have any suitable number of teeth. Alternatively, the ring gear can be formed of a suitable plastic such as Nylon™. The other portions of the backflow adapter 21 as, for example, the body 22, the first collar 31, the second collar 34, the retaining ring 48 can be formed of a suitable plastic such as polycarbonate. The metal parts such as the rod 62, the stabilization rod 76 and the spring 81 can be formed of a suitable material such as stainless steel.

[0026] Means is provided for introducing liquid as, for example, a radiopaque liquid, into the bore 86 and consists of a tube 91 formed of a suitable material such as plastic extending through the first collar 31 and through the sheath tube adapter 26 so that it is in communication with the bore 86. Flexible tubing 92 is connected to the tube 91 and has a stopcock 93 of a conventional type mounted thereon which is provided with a Luer-type fitting 94. The stopcock 93 is provided with a knob 96 which can be utilized for moving the stopcock 93 between open and closed positions.

[0027] A sheath introducer 101 is provided as a part of the assembly shown in Figure 1 and as shown in Figure 2 consists of an elongate tubular member 102 formed in three sections 103, 104 and 106 of different diameters.

[0028] The elongate tubular member 102 can be formed of a suitable plastic material such as Pebax™ which is formed of polyether Block Amides which is loaded with approximately 10% barium sulfate to make

the same visible under X-rays. Section 103 can have a diameter ranging from 0.381 cm to 0.762 cm (0.15" to 0.30") and preferably an outside diameter of 0.47625 cm (3/16ths of an inch). The section 104 can have a suitable diameter as, for example, 0.2032 cm to 0.381 cm (0.08" to 0.15") and preferably a diameter of 0.3175 cm (1/8th of all inch). The section 106 can have a diameter ranging from 0.1524 cm to 0.3048 cm (0.06" to 0.12") and preferably a diameter of 0.2032 cm (0.08"). The distal extremities of the sections 103 and 104 are provided with tapers 107 and 108, respectively, so as to provide a tapered transition from one diameter to another. A Luer-type fitting 111 is mounted on the proximal extremity of the tubular section 103. A bore or lumen 112 (see Figure 4) of a suitable size as, for example, one capable of passing 0.09652 cm (0.038") guidewire, is provided in the section 106 as well as in the sections 104 and 103 extending the length of the tubular member 102. A tube 116 is mounted on the section 106 and the distal extremity of the same and is formed of a suitable material such as silicone and is retained thereon in a suitable matter by the use of polyethylene shrink tubing 117. A cylindrical enlargement or annular bump 121 is provided on the tubular section 106 adjacent the distal extremity of the shrink tubing 117 and serves to prevent the sleeve 116 and the shrink tubing 117 from accidentally slipping off of the distal extremity of the tubular section 106.

[0029] When the sheath introducer 101 is disposed in the expandable sheath 11, as shown in Figure 1, the proximal extremity of the silicone sleeve 116 is disposed over the distal extremity of the sheath tube 12 and serves to prevent the sharp edges of the folded sheath tube 12 from causing trauma to the interior wall of a vessel when it is introduced into the vessel when the sheath is introduced as hereinafter described. A vent hole 123 is provided in the sheath introducer 101 which is in communication with the passage 112 proximal of the silicone sleeve 116 as shown in Figure 3. The vent hole 123 can be utilized for flushing the elongate sheath tube 12 through the side port fitting 94 prior to use of the expandable sheath in a surgical procedure.

[0030] Operation and use of the expandable sheath 11 in conjunction with the sheath introducer 101 may now be briefly described as follows. Let it be assumed that the patient has been prepared in a conventional manner and that it is desired to enter a peripheral vessel such as an artery or a vein of the patient. The desired vessel is exposed and a longitudinal or transverse incision made into that vessel. A guidewire of a suitable size is then selected as, for example, a guidewire having a diameter of 0.09652 cm (0.038"). The guidewire (not shown) is introduced into the vessel and then the expandable sheath assembly 11 shown in Figure 1 is placed over the guidewire by placing the proximal extremity of the guidewire into the lumen 112 provided in the elongate tubular member 102 and advanced through the Luer fitting 111. The rounded tip and the

small diameter of the section 106 of the tubular member 102 facilitate advancement of the sheath introducer 101 into the vessel without traumatizing the vessel. The small-diameter tip section 106 is followed by the elongate sheath tube 12 which has been collapsed as hereinafter described about the tubular section 106 until the sheath tube 12 has been introduced to the proper depth in the vessel. As soon as the sheath tube 12 has been positioned in the vessel, the sheath introducer 101 is advanced relative to the elongate sheath tube 12 by using one hand to hold the backflow adapter 21 which is connected to the sheath tube 12 and the other hand to push the sheath introducer 101 so that the proximal extremity of the silicone sleeve 116 moves off of the distal extremity of the sheath tube 12 to expose the same.

[0031] As soon as this has been accomplished, the sheath introducer 101 is pushed forward so that section 103 enters the collapsed section of the sheath tube 12 to commence opening of the same. The sheath introducer 101 is then removed through the backflow adapter 21. The sheath introducer can be removed by grasping the backflow adapter 21 by the fingers of the hand as hereinafter described to at least partially open the same to permit removal of the sheath introducer and dilator 101 while minimizing the flow of blood from the sheath tube 12. The backflow adapter can then be released. The sheath 11 and its backflow adapter is now in its normally closed state to provide a hemostatic seal closing the flow passage 86.

[0032] The physician conducting the procedure then selects the desired catheter or other device which is desired to be introduced through the expandable sheath 11. Such a device should have a diameter of 8.5 mm or less or which is at least slightly less than the diameter of the bore 86. The physician grasps the actuator members 66 and 71 and presses the same to operate the rack 61 to open the diaphragm or valve member 40 permitting the physician to insert the device as, for example, the catheter through the expandable sheath 11. As soon as the catheter has been advanced as far as desired, the physician releases the pressure on the actuator members 66 and 71 permitting the diaphragm 40 to close around the device as, for example, the catheter inserted through to form a hemostatic seal about the catheter. If it is desired to reposition the catheter, it is merely necessary to push or pull the catheter and it will slide freely through the diaphragm. When it is desired to remove the catheter, the catheter need only be pulled out of the sheath 101 and the diaphragm will seal closed forming a hemostatic seal.

[0033] After the procedure has been completed, the expandable sheath 11 can be removed from the vessel and the incision which has been made in the vessel for permitting passage of the expandable sheath can be sutured.

[0034] It can be seen from the foregoing that there has been provided an expandable sheath 11 which can be made in various sizes to accommodate large-diameter

devices while still providing the desired hemostatic seal. The expandable sheath can be readily inserted and removed. The sheath introducer 101 facilitates this introduction. It is provided with a distal extremity 106 which is small in diameter to permit the sheath tube 12 to be wrapped about the same as hereinbefore described. The sheath introducer 101 is provided with sections 103 and 104 of larger diameters to provide additional rigidity to the sheath introducer 101 to facilitate pushing of the sheath introducer when introducing the expandable sheath 11 into the vessel of the patient.

[0035] An alternative mechanism for actuating the diaphragm 40 is shown in Figure 17 and consists of a pinion 131 which engages the ring gear 36 and is disposed in a cylindrical recess 132 provided in the body 22. The pinion 131 is mounted on a shaft 133. Another gear 134 is mounted on the shaft 133 and has a smaller diameter than the diameter of the pinion 131 and engages the rack teeth 64 provided on the rod 62. By providing such a gear arrangement, it can be seen that it is possible to provide a shorter rack to achieve the same degree of ring gear rotation for opening and closing of the diaphragm 40.

[0036] As can be seen in Figures 18 and 19, there is shown another embodiment of a mechanism for actuating the diaphragm 40. As shown therein it consists of a flexible rack 141 that is comprised of a flexible member 142 which is provided with rack teeth 143 on one side of the same which are adaptable to engage the ring gear 36. The member 142 extends through a semicircular slot 144 provided in the body so that it extends through the body and around the ring gear 36. An actuator 146 is provided formed integral with the rack 141 for operating the rack 141 with the fingers of the hand. In this construction the rack is substantially contained within the body 22.

Claims

1. A large-diameter expandable sheath assembly for use in introducing a catheter into a vessel in a body of a patient comprising an elongate sheath tube (12) formed of a flexible material having proximal and distal extremities (13, 14) and having a passage (16) extending therethrough of a maximum predetermined diameter; and a backflow adapter (21) secured to the proximal extremity (13) of the elongate sheath tube (12), said backflow adapter (21) having a central opening (23) therein in registration with the passage (16) in the sheath tube (12) and valve means disposed in the said central opening (23) of the backflow adapter (21) and movable between an open position in which the catheter is permitted to be inserted into the sheath and a closed position in which the valve means serves to form a hemostatic seal about the catheter, the valve means being in the form of a cylindrical member (40) formed of a flexible material and having a bore (41) therein in registration with the central opening (23), together with means (46, 47) carried by the backflow adapter (21) for engaging opposite ends (42, 43) of said cylindrical member (40) to enable one of said ends (42) to be rotated relative to the other (43) thereby twisting the cylindrical member (40) and closing the bore (41), said means for enabling relative rotation between opposite ends of said cylindrical member (40) including a retaining ring (48) and sheath tube adapter (26) secured to opposite ends of said cylindrical member (40), means for fixing the sheath tube adapter (26) to prevent rotation of the same within the backflow adapter (21) and means carried by the backflow adapter (21) for rotating the retaining ring (48) with respect to the sheath tube adapter (26), characterised in that said means for enabling relative rotation between opposite ends of said cylindrical member (40) further includes a ring gear (36) secured to said retaining ring (48) and rack means (61) for driving said ring gear (36) to cause rotation of the same.
2. A sheath assembly as claimed in claim 1 together with means (81) yieldably engaging said rack means (61) for urging said rack means (61) into a position wherein said cylindrical member (40) is moved to provide valve means which is in a normally closed position.
3. A sheath assembly as claimed in claim 2, wherein said rack means (61) extends tangentially through said backflow adapter (21) together with actuator means (66) carried by the rack means (61) and adapted to be engaged by the fingers of the hand for moving the rack means (61) against the force of the yieldable means (81) to move the valve means to an open position.
4. A sheath assembly as claimed in claim 3 together with a stabilizer rod (76) slidably mounted within said backflow adapter (21) parallel to said rack means (61) and secured to said actuator means (66).
5. A sheath assembly as claimed in claim 4 together with means (83) carried by the rack means (61) for preventing said yieldable means (81) from pulling said rack means (61) out of engagement with said cylindrical member (40).
6. A sheath assembly as claimed in claim 1, wherein the distal extremity (14) of the elongate sheath tube (12) is folded longitudinally to a smaller folded diameter.
7. A sheath assembly as claimed in claim 6 together with a sheath introducer (101) disposed in the pas-

sage (16) in the sheath tube (12), said sheath introducer (101) having a distal extremity extending beyond the proximal extremity (13) of the sheath tube (12) and dilation means (121) mounted on said distal extremity of the sheath introducer (101) which has a diameter greater than the folded diameter of the sheath tube (12).

Patentansprüche

1. Expandierbare Hüllenanordnung großen Durchmessers zum Gebrauch beim Einführen eines Katheters in ein Gefäß in einem Körper eines Patienten, umfassend ein aus einem flexiblen Material hergestelltes längliches Hüllrohr (12) mit einem proximalen und einem distalen Ende (13, 14) und mit einem sich durch dieses erstreckenden Durchgang (16) mit einem maximalen vorbestimmten Durchmesser; und einen am proximalen Ende (13) des länglichen Hüllrohres (12) befestigten Rückflußadapter (21), wobei der Rückflußadapter (21) eine zentrale Öffnung (23) in Ausrichtung zu dem Durchgang (16) im Hüllrohr (12) und ein Ventilmittel aufweist, welches in der zentralen Öffnung (23) des Rückflußadapters (21) angeordnet ist und zwischen einer offenen Stellung, in welcher es möglich ist, den Katheter in die Hülle einzuführen, und einer geschlossenen Stellung bewegbar ist, in welcher das Ventilmittel dazu dient, eine hämostatische Dichtung um den Katheter herum auszubilden, wobei das Ventilmittel in Form eines Zylinderelements (40) ausgebildet ist, welches aus einem flexiblen Material hergestellt ist und eine Bohrung (41) in Ausrichtung zu der zentralen Öffnung (43) aufweist, zusammen mit vom Rückflußadapter (21) getragenen Mitteln (46, 47) zum Angreifen an entgegengesetzten Enden (42, 43) des Zylinderelements (40), um zu ermöglichen, daß eines der Enden (42) relativ zum anderen (43) gedreht wird, wodurch das Zylinderelement (40) verdreht wird und die Bohrung (41) geschlossen wird, wobei das Mittel zum Ermöglichen einer Relativdrehung zwischen entgegengesetzten Enden des Zylinderelements (40) an den entgegengesetzten Enden des Zylinderelements (40) befestigt einen Haltering (48) und einen Hüllrohradapter (26), Mittel zum Befestigen des Hüllrohradapters (26) zum Verhindern einer Drehung desselben innerhalb des Rückflußadapters (21) und vom Rückflußadapter (21) getragene Mittel zum Drehen des Halterings (48) bezüglich des Hüllrohradapters (26) umfaßt, **dadurch gekennzeichnet**, daß das Mittel zum Ermöglichen einer Relativdrehung zwischen den entgegengesetzten Enden des Zylinderelements (40) ferner ein am Haltering (48) befestigtes Ringzahnrad (36) und ein Zahnstangenmittel (61) zum Antreiben des Ringzahnrad (36) aufweist, um eine Drehung dessel-

ben zu bewirken.

2. Hüllenanordnung nach Anspruch 1, zusammen mit Mitteln (81), welche nachgebend am Zahnstangenmittel (61) angreifen, um das Zahnstangenmittel (61) in eine Stellung zu drücken, wobei das Zylinderelement (40) bewegt wird, um ein Ventilmittel vorzusehen, welches sich normalerweise im geschlossenen Zustand befindet.
3. Hüllenanordnung nach Anspruch 2, wobei sich das Zahnstangenmittel (61) tangential durch den Rückflußadapter (21) zusammen mit einem Bedienelement (66) erstreckt, welches vom Zahnstangenmittel (61) getragen und dazu ausgelegt ist, von den Fingern der Hand zur Bewegung des Zahnstangenmittels (61) gegen die Kraft der nachgebenden Mittel (81) ergriffen zu werden, um das Ventilmittel in eine geöffnete Stellung zu bewegen.
4. Hüllenanordnung nach Anspruch 3, zusammen mit einer Stabilisatorstange (76), welche verschiebbar im Rückflußadapter (21) parallel zum Zahnstangenmittel (61) angebracht und am Bedienelement (66) befestigt ist.
5. Hüllenanordnung nach Anspruch 4, zusammen mit einem Mittel (83), welches vom Zahnstangenmittel (61) getragen ist, um zu verhindern, daß das nachgebende Mittel (81) das Zahnstangenmittel (61) außer Eingriff mit dem Zylinderelement (40) zieht.
6. Hüllenanordnung nach Anspruch 1, wobei das distale Ende (14) des länglichen Hüllrohres (12) in Längsrichtung auf einen kleineren gefalteten Durchmesser zusammengeklappt ist.
7. Hüllenanordnung nach Anspruch 6, zusammen mit einer im Durchgang (16) im Hüllrohr (12) angeordneten Hülleneinführvorrichtung (101), wobei die Hülleneinführvorrichtung (101) ein distales Ende aufweist, welches sich über das proximale Ende (13) des Hüllrohres (12) hinaus erstreckt und ein am distalen Ende der Hülleneinführvorrichtung (101) angebrachtes Dilatationsmittel (121) umfaßt, welches einen Durchmesser aufweist, der größer als der zusammengeklappte Durchmesser des Hüllrohres (12) ist.

Revendications

1. Ensemble formant gaine extensible de grand diamètre destiné à être utilisé pour introduire un cathéter dans un vaisseau dans le corps d'un patient comprenant un tube formant gaine allongé (12) formé en matériau souple ayant des extrémités proximale et distale (13, 14) et comportant un pas-

sage (16) s'étendant au travers d'un diamètre maximal prédéterminé, et un adaptateur antireflux (21) fixé à l'extrémité proximale (13) du tube formant gaine allongé (12), ledit adaptateur antireflux (21) présentant une ouverture centrale (23) dans celui-ci correspondant au passage (16) dans le tube formant gaine (12) et des moyens formant clapet disposés dans ladite ouverture centrale (23) de l'adaptateur antireflux (21) et mobile entre une position ouverte dans laquelle le cathéter peut être inséré dans la gaine et une position fermée dans laquelle les moyens formant clapet servent à former un joint hémostatique autour du cathéter, les moyens formant clapet se présentant sous la forme d'un élément cylindrique (40) formé en matériau souple et comportant un alésage (41) dans celui-ci correspondant à l'ouverture centrale (23), conjointement avec des moyens (46, 47) supportés par l'adaptateur antireflux (21) pour venir en prise avec les extrémités opposées (42, 43) dudit élément cylindrique (40) pour permettre à l'une desdites extrémités (42) de tourner l'une par rapport à l'autre (43), tordant de cette manière l'élément cylindrique (40) et fermant l'alésage (41), lesdits moyens pour permettre une rotation relative entre les extrémités opposées dudit élément cylindrique (40) comprenant une bague de retenue (48) et un adaptateur pour tube formant gaine (26) fixés au niveau des extrémités opposées dudit élément cylindrique (40), des moyens pour fixer l'adaptateur pour tube formant gaine (26) afin d'empêcher la rotation de celui-ci à l'intérieur de l'adaptateur antireflux (21) et des moyens supportés par l'adaptateur antireflux (21) pour faire tourner la bague de retenue (48) par rapport à l'adaptateur pour tube formant gaine (26), caractérisé en ce que lesdits moyens pour permettre une rotation relative entre les extrémités opposées dudit élément cylindrique (40) comprennent en outre une couronne dentée (36) fixée à ladite bague de retenue (48) et des moyens formant crémaillère (61) pour amener ladite couronne dentée (36) à effectuer une rotation.

2. Ensemble formant gaine selon la revendication 1, conjointement avec des moyens (81) venant en prise de manière à pouvoir céder avec lesdits moyens formant crémaillère (61) afin de pousser lesdits moyens formant crémaillère (61) dans une position dans laquelle ledit élément cylindrique (40) est déplacé pour fournir des moyens formant clapet qui sont dans une position normalement fermée.
3. Ensemble formant gaine selon la revendication 2, dans lequel lesdits moyens formant crémaillère (61) s'étendent de manière tangentielle dans ledit adaptateur antireflux (21) conjointement avec les moyens d'actionnement (66) supportés par les moyens formant crémaillère (61) et adaptés pour

être mis en prise avec les doigts de la main afin de déplacer les moyens formant crémaillère (61) à l'encontre d'une force des moyens destinés à pouvoir céder (81) afin de déplacer les moyens formant clapet dans une position ouverte.

4. Ensemble formant gaine selon la revendication 3, conjointement avec une tige stabilisatrice (76) montée de manière à glisser à l'intérieur dudit adaptateur antireflux (21) parallèlement auxdits moyens formant crémaillère (61) et fixée auxdits moyens d'actionnement (66).
5. Ensemble formant gaine selon la revendication 4, conjointement avec des moyens (83) supportés par les moyens formant crémaillère (61) pour empêcher lesdits moyens destinés à céder (81) de tirer lesdits moyens formant crémaillère (61) et de les désolidariser dudit élément cylindrique (40).
6. Ensemble formant gaine selon la revendication 1, dans lequel l'extrémité distale (14) du tube formant gaine allongé (12) est repliée longitudinalement jusqu'à obtenir un diamètre replié plus petit.
7. Ensemble formant gaine selon la revendication 6, conjointement avec un dispositif d'introduction de gaine (101) disposé dans le passage (16) à l'intérieur du tube formant gaine (12), ledit dispositif d'introduction de gaine (101) ayant une extrémité distale s'étendant au-delà de l'extrémité proximale (13) du tube formant gaine (12) et des moyens de dilatation (121) montés sur ladite extrémité distale du dispositif d'introduction de gaine (101) qui présente un diamètre supérieur au diamètre replié du tube formant gaine (12).
